

## VERTICAL EVACUATION OF TESSIER® SITSKI EQUIPMENTS

Thanks to the different tests realized, a unique evacuation procedure for all sitski equipment homologated in France has been defined. It is approved by the French homologation commission presided by the STRMTG.

Two anchor straps of 1m50 (example : anchor strap PETZL C40-150) are necessary.

The first strap will put behind the backrest of the sitski and under the seated skier's arms. The second will be put under the frame at the level of the skier's knees, passing in a part of the frame which will keep the strap from sliding backward.

Both straps will join in one hanging point where will come the karabiner of the rope used for the evacuation.

The evacuation triangle, usually used to evacuate people, can be then used to secure the accompanist of the seated skier who can be active during the evacuation, also when the safety rail is open. It is indispensable to secure the accompanist before opening the safety rail.

In France, as in many European countries, the equipment used for evacuation are property of the ski patrols. So skiers and first-aid workers have the guarantee to use gear in perfect shape (stored in a bag to be protected from exterior aggressions, checked every year, with a defined lifetime and replaced when necessary).
